FAQ

Q1: What are the different types of mathematical models used in engineering systems modelling and control?

A1: Many different mathematical models are used, ranging from simple transfer

functions (suitable for linear systems) to complex differential equations (for nonlinear systems). Other models include state-space representations, which provide a concise description of the system's internal states, and discrete-time models used for digital control systems. The choice of model depends on the system's complexity and the required level of accuracy.

Q2: How do I choose the right control strategy for a specific application?

A2: The selection of a suitable control strategy depends on several factors, including the system's characteristics (linearity, stability, time constants), performance requirements (accuracy, speed of response), and constraints (limits on input signals, actuator capabilities). Simple systems may be adequately controlled using PID controllers, while complex systems may require more advanced techniques like MPC. A thorough understanding of the system's dynamics is essential for making an informed decision.
